

**DEVICE AND METHOD FOR MAKING PRECISE MEASUREMENTS
AND CUTS WITH A MEASURING TAPE**

Nicholas F. Baida

09/11/2000

Field of the Invention

[0001] The present invention relates to the field of tape measures.

Background of the Invention

[0002] There is a need for a device that allows one-handed precision measurements to be performed while the item being measured is also marked with one hand. The common measuring tape, commonly used in construction, for which the inventive improvement is proposed, has evolved over the last one hundred years into an easily operated tool familiar to millions of people. Its use, however, requires the use of two hands, one for holding the measuring tape and the other for marking the item being measured.

[0003] As is well known, typical prior art measuring tape devices have a measuring tape element, which is rolled up and enclosed in a standard rectangular case. The tape is rolled up inside the case with one of its two ends affixed inside the case to prevent it from slipping out. The second, free end of the tape element is capped by a used to hook the tape element to edges of surfaces being measured. The lip is also functions to prevent the second end from being pulled inside the case. The tape element is marked with markings having associated numbers, which indicate exact distance from that notch to the lip. The case has a case surface from which the tape protrudes and a surface on which the hold/release knob is located. The hold/release knob permits the tape element to unroll, rollup, or be held in place while in the unrolled state.

[0004] Numerous unsuccessful attempts have been made to improve the measuring tape to unable making measurements with one hand. For example, U.S. Patent No. 5,154,006 adds to a standard measuring tape a clip for holding a pencil which can be used to make markings after a surface distance has been measured. This approach is supposed to allow a workman to make a measurement and leave a mark using only one hand. However, because of the free movement of the clipped pencil, the measurement itself is not precise and the pencil is not safe from breakage if kept with other tools as is commonly done.

[0005] An attempted improvement on the above design was made in the U.S. Patent No. 5,671,543, where the pencil could be affixed to the measuring tape in such a way that it will not be moved by a slight force. The problem with this approach is that it was designed for a carpenter's pencil, which is quite large and the whole device is bulky because the structure holding the pencils is also quite large. Holding the device is also uncomfortable and the storage of such device with other tools would usually either break the pencil or break the marking tip off the pencil. Additional time would be required either to sharpen the pencil or to replace it. If the pencil breaks as it is being used, the workman will have to stop all work and use two hands to move the pencil to its proper position.

[0006] U. S. Patent 4,542,589 offers a solution to the problem of the pencil size by putting it inside the casing of the measuring tape. However, the marking pencil is put in such a way as to force the workman to bend the measuring tape every time the mark is to be made. Bending increases the wear and tear on the measuring tape. The measuring tape can easily be bent over or under the location of the wanted mark, therefore, the precision of the measurement can not be guaranteed. Moreover, valuable time must be wasted when the workman is forced to repeat the marking step over and over until the correct mark is found.

[0007] Finally, U.S. Patent No. 4,760,648 adds a clip to a tape measure, which holds a pencil on a support which is secured to one side of the tape measure housing. This pencil and support extend from the tape measure and therefore can be easily bent and damaged when stored with other tools. This would easily cause the loss of precision of the measurement and unnecessarily waste time in fixing the pencil. The pencil can neither be fixed nor placed in a proper position with only one hand.

[0008] Therefore, the invention overcomes the various problems of the prior art by providing a device that allows the workman to make measurements, with a precision measuring to the smallest fraction increment on the tape of the tape measuring device. That device, furthermore, should not lose its precision with common wear and tear of the measuring tape or increase the wear and tear on the tape by forcing a bending of the tape,

and allow the measurements to be achieved and the measured surface to be marked with one hand. The invention can also enable all the marking and cutting elements to be more flush and integrated into a tape measure case than is known.

[0009] It is also the purpose of this invention to retrofit existing measuring tapes purchased by millions of people and allow those measuring tape devices to be used as described above for making precise measurements while using only one hand, by using the additional embodiment with a shell casing which encloses a standard tape measure.

SUMMARY OF THE INVENTION

[0010] The invention relates to a shell casing for enclosing a case of a tape measure comprising a first concave shell with malleable interior sections a second concave shell with malleable interior sections; and adjustable connection means for connecting said first concave shell to said second concave shell thereby enclosing the case of the tape measure. A razor blade may be also connected to at least one of said concave shells. The razor blade may be a retractable razor blade, and may be molded into at least one of said concave shells wherein said retractable razor blade is molded flush within said concave shell. A lead pencil may be connected to at least one of said concave shells. A retractable lead pencil molded into at least one of said concave shells may be used wherein said retractable lead pencil is molded flush within said concave shell.

[0011] The invention also relates to a combination tool comprising a tape measure in a case with a retractable cutting blade located inside said case and arranged to make cuts corresponding to measurement increments arranged on said tape measure. Said tape measure may include a nail hole at its exposed end. Said retractable pencil may be adapted to use interchangeable leads or limestone. Said retractable lead pencil is a mechanical lead pencil molded into said case in a flush manner. A clear indicator window may be located proximate to the tape with an index line located in line with said measurement increments. Also, a measurement mark made be made in pencil by extending a retractable pencil lead corresponding to said measurement marks on said tape measure.

[0012] The invention also discloses a method of making a cut in the object at a measured distance by extending a retractable blade located inside said case wherein said blade is arranged to make cuts corresponding to measurement increments arranged on said tape measure. Viewing can also be enabled and accomplished through a clear window located or positioned above said measurement increments to view and line up said measurement increments with an index line which corresponds measurement increments on said tape measure. The method may also include the steps of including a nail hole in said tape measure at an exposed end and inserting a nail through said nail hole into the object, and rotating said case about the nail in an arc to make a circular measured cut in the object.

BRIEF DESCRIPTION OF DRAWINGS

- [0013] Figure 1 is an isometric view of an embodiment of the present invention.
- [0014] Figure 2a is a plan view of the end of an embodiment of the present invention measuring tape with a hole at the exact zero measurement point for inserting a nail.
- [0015] Figure 2b is a front view of an embodiment of the end of the present invention measuring tape showing insertion of a nail.
- [0016] Figure 2c is a side view of an embodiment of the end of the present invention measuring tape showing insertion of a nail.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS OF THE INVENTION

[0036] The present invention is at least an improvement on a commonly used measuring tape device. The invention allows for measurements and measurement marks or cuts to be made with precision, measuring to the smallest fraction of the marking of a tape measure. The invention also enables measurements and cuts with a blade to be made and the measured on a surface to be marked using one hand.

[0037] Figures 8g-8k show the preferred embodiment of a precision unit 30 according to the present invention. The unit has a top surface 31, back surface 32, a side surface 34, and a bottom surface 36. Additionally, the precision unit 30 includes a marker housing part 38 with a marker hold/release part 40 to allow the marker 42 to slide in and out of the marker housing part. Proximate to the bottom surface 36 of the unit is a viewing window 26 that includes an indicator line 44 that is inline with marker 42 and knife blade 28 and proximate to a tape thread part wherein the measuring tape element 12 exits the precision unit 30. A viewing window 26 is provided for viewing the measuring tape element 12. In the preferred embodiment the material used for the precision unit 30 is plastic. The reason for the viewing window 26 to be made from clear material is so that a user can view the tape measure located below the viewing window 26 which is inline with the inline with marker 42 and knife blade 28. Thereafter, the user can make a mark with the marker 42 and/or make a cut with the knife blade 28. For example, the tool may be used to measure and cut sheetrock.

[0038] The marker holding part 38 can be circular in its cross section or as shown in Figure 7, or it can be rectangular as shown in Fig. 8i. The marker holding part 38 is hollow and includes a partial cutout 48 preferably located on a side most easily accessible to the workman's thumb or finger, while the precision unit 30 is held in the palm of the hand. The hold/release part 40 is attached to a marker 42 and is inserted into the hollow opening 48. With a twist of a user's finger, the hold/release part 40 releases the marker to move it down the marker housing part 38 far enough to make a mark on a surface being measured. When the user is assured that the marker 42 is moved far enough to make a

mark, the hold/release part 40 can be manipulated to fasten the marker 42 in place. The marker housing part 38 and its hollow opening 48 is positioned relative to unit 30 in such a manner as to assure that any mark made by the marker 42 on the surface being measured coincides or exactly overlaps the location of the indicator line 44 on the bottom surface 36.

[0039] The location of the side surface 34 and of the marker holding part 38 can be alternated depending on the workman's preference. The marker hold/release part 40 can be any fastener that enables easy release and/or holding of the marker with only a thumb or a finger, while the rest of the hand is used for holding the measuring tape element 12 without requiring use of the other hand.

[0040] After positioning the precision unit to a position where a mark should be made, the user uses a thumb or another finger, depending on how the measuring tape is grasped, on marker hold/release part 40 to move the marker 42 down the marker holding part 38 and to fasten it in place. Looking through the viewing window 26 the user makes sure that the indicator line 44 coincides with the exact measurement mark 18 on the tape element 12. All that is left now is to make a slight wrist movement of the hand holding the tape measure, against a surface being measured to make a mark with the marker 42.

[0041] Moreover, the present invention is capable of making, cutting, or marking, precision measured circles or arcs, again using only one hand if need be. This can be achieved in the following way: attaching the lip 16 of the measuring tape element 12 to a surface, this can be achieved, for example, by hooking it on a pre-existing staple or nail or nailing it in through the hole 8, extending the tape to a desired radius, using one hand to adjust the marker hold/release part 40 and drawing a partial or full circle (not shown).

[0042] Reference is now made to an alternative embodiment shown in Figures 1, 3, 4, and 5. This embodiment uses a first concave shell casing 2 and a second concave shell casing 4 which are placed together to surround a standard sized rectangular hand held tape measure. A standard sized tape measure may be various sizes, but for example, the encased standard tape measure may be 3"x3"x1". The invention contemplates providing different sized shell casings for larger or smaller tape measures as needed. As shown in
